Under the Hood of X

OLS (and regression methods more generally) requires:

- X is full column rank.
- N > K.

Intro

• "Sufficient" variability in **X**.

"Perfect" Multicollinearity

First a formal definition:

There cannot be any set of λ s such that:

$$\lambda_0 \mathbf{1} + \lambda_1 \mathbf{X}_1 + \ldots + \lambda_K \mathbf{X}_K = \mathbf{0}$$

A Toy Model

Let's see if there is a relationship between gas milage and car performance.

```
> data("mtcars")
> model1 <- lm(qsec ~ mpg, mtcars)
> summary(model1)
Call:
lm(formula = qsec ~ mpg, data = mtcars)
Residuals:
   Min
            1Q Median
                                   Max
-2.8161 -1.0287 0.0954 0.8623 4.7149
Coefficients:
           Estimate Std. Error t value Pr(>|t|)
(Intercept) 15.35477    1.02978    14.911    2.05e-15 ***
            0.12414 0.04916 2.525 0.0171 *
mpg
Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
Residual standard error: 1.65 on 30 degrees of freedom
Multiple R-squared: 0.1753, Adjusted R-squared: 0.1478
F-statistic: 6.377 on 1 and 30 DF, p-value: 0.01708
```

A Toy Model

Now let's redo that using Kilograms/Liter instead of Miles/Gallon, but accidentally include both measures as predictor variables. What happens?

```
> mtcars$kgL <- mtcars$mpg * .425
> model2 <- lm(qsec ~ mpg + kgL, mtcars)
> summary(model2)
Call:
lm(formula = qsec ~ mpg + kgL, data = mtcars)
Residuals:
    Min
            1Q Median
                                    Max
-2.8161 -1.0287 0.0954 0.8623 4.7149
Coefficients: (1 not defined because of singularities)
           Estimate Std. Error t value Pr(>|t|)
(Intercept) 15.35477    1.02978    14.911    2.05e-15 ***
            0.12414
mpg
                     0.04916
                                 2.525
                                         0.0171 *
                                    NA
                                             NA
kgL
                 NA
                            NA
Signif. codes: 0 '*** 0.001 '** 0.01 '* 0.05 '.' 0.1 ' ' 1
Residual standard error: 1.65 on 30 degrees of freedom
Multiple R-squared: 0.1753, Adjusted R-squared: 0.1478
F-statistic: 6.377 on 1 and 30 DF, p-value: 0.01708
```

- 1. Perfect Multicollinearity is a very big problem (Theoretically)
- Prefect Multicollinearity is NOT a problem at all (In Practice)

N > K

- Statistically, if N < K, then:
 - We lack sufficient degrees of freedom to identify $\hat{\boldsymbol{\beta}}.^*$
 - $\hat{\boldsymbol{\beta}}$ is "overdetermined."
- Conceptually, N < K means that:
 - Our number of variables > Cases
 - Which means there can be no unique conclusion about explanatory / causal factors.

*Note: "identification" is used in statistics and econometrics to mean several different things, I am using it here in the most basic sense to mean that the parameters (here the $\hat{\beta}$ s) cannot be determined from the variables

Another Toy Model

Let's subset the mtcars data to only look at lightweight cars and add some more predictor variables:

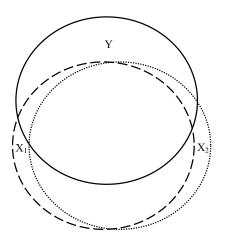

```
> rm(list=ls())
> data("mtcars")
> lightweight <- subset(mtcars, wt<2)
> model3 <- with(lightweight, lm(qsec ~ mpg + disp + hp))
> summary(model3)
Call:
lm(formula = qsec ~ mpg + disp + hp)
Residuals:
ALL 4 residuals are 0: no residual degrees of freedom!
Coefficients:
            Estimate Std. Error t value Pr(>|t|)
(Intercept) 39.54944
                            NaN
                                    NaN
                                             NaN
            -0.14716
                                   NaN
mpg
                            NaN
                                             NaN
          -0.25649
                                   NaN
                                             NaN
disp
                            NaN
            0.05502
                            NaN
                                   NaN
                                             NaN
hp
Residual standard error: NaN on O degrees of freedom
Multiple R-squared:
                        1, Adjusted R-squared:
                                                  NaN
F-statistic: NaN on 3 and 0 DF, p-value: NA
```

What Does This Tell Us?

As with "perfect" multicollinearity, having N > K will result in a model specification that is impossible to estimate. Thus, you cannot violate this assumption in practice

Intuition

N > K

High (Non-Perfect) Multicollinearity

Recall that

$$\widehat{\mathsf{Var}(\hat{oldsymbol{eta}})} = \hat{\sigma}^2 (\mathbf{X}'\mathbf{X})^{-1}$$

We can write the kth diagonal element of $(\mathbf{X}'\mathbf{X})^{-1}$ as:

$$\frac{1}{(\mathsf{X}_k'\mathsf{X}_k)(1-\hat{R}_k^2)}$$

where \hat{R}_k^2 is the R^2 from the regression of \mathbf{X}_k on all the other variables in \mathbf{X} .

N > K

Things to understand:

- Multicollinearity is a sample problem.
- 2. Multicollinearity is a matter of degree.

(Near-Perfect) Multicollinearity: Detection

- 1. High R^2 , but nonsignificant coefficients.
- 2. High pairwise correlations among independent variables.
- 3. High partial correlations among the Xs.
- 4. VIF and Tolerance.

VIF / Tolerance

If $\hat{R}_k^2 = 0$, then

$$\widehat{\mathsf{Var}(\hat{\beta}_k)} = \frac{\hat{\sigma}^2}{\mathsf{X}'_k \mathsf{X}_k};$$

So:

$$\mathsf{VIF}_k = \frac{1}{1 - \hat{R}_k^2}$$

$$\mathsf{Tolerance} = \frac{1}{\mathsf{VIF}_k}$$

Rule of Thumb: VIF > 10 is a problem.

What To Do?

N > K

Don't:

- Blindly drop covariates!!!
- Restrict βs...

Do:

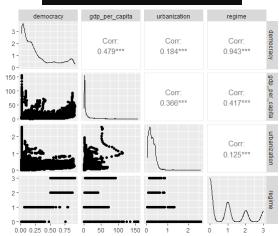

- Add data.
- Transform the covariates
 - Data reduction
 - First differences
 - Orthogonalize
- Shrinkage / Regularization Methods
